Metabolic plasticity of IDH1-*mutant* glioma cell lines is responsible for low sensitivity to glutaminase inhibition

Victor Ruiz-Rodado¹, Adrian Lita¹, Tyrone Dowdy¹, Orieta Celiku¹, Alejandra Cavazos Saldana¹, Herui Wang¹, Chun Zhang Yang¹, Raj Chari², Aiguo Li¹, Wei Zhang¹, Hua Song¹, Meili Zhang¹, Susie Ahn¹, Dionne Davis¹, Xiang Chen³, Zhengping Zhuang¹, Christel Herold-Mende⁴, Kylie J. Walters³, Mark R. Gilbert¹ and Mioara Larion^{1*}

Abstract

Background: Targeting glutamine metabolism in cancer has become an increasingly vibrant area of research. Mutant IDH1 (IDH1^{mut}) gliomas are considered good candidates for targeting this pathway because of the contribution of glutamine to their newly acquired function: synthesis of 2-hydroxyglutarate (2HG).

Methods: We have employed a combination of ¹³C tracers including glutamine and glucose for investigating the metabolism of patient-derived IDH1^{mut} glioma cell lines through NMR and LC/MS. Additionally, genetic loss-of-function (in vitro and in vivo) approaches were performed to unravel the adaptability of these cell lines to the inhibition of glutaminase activity.

Results: We report the adaptability of IDH1^{mut} cells' metabolism to the inhibition of glutamine/glutamate pathway. The glutaminase inhibitor CB839 generated a decrease in the production of the downstream metabolites of glutamate, including those involved in the TCA cycle and 2HG. However, this effect on metabolism was not extended to viability; rather, our patient-derived IDH1^{mut} cell lines display a metabolic plasticity that allows them to overcome glutaminase inhibition.

Conclusions: Major metabolic adaptations involved pathways that can generate glutamate by using alternative substrates from glutamine, such as alanine or aspartate. Indeed, asparagine synthetase was upregulated both in vivo and in vitro revealing a new potential therapeutic target for a combinatory approach with CB839 against IDH1^{mut} gliomas.

Keywords: IDH1-mutant, Gliomas, Glutaminase, CB839, AGI5198, ¹³C tracing

Background

Isocitrate dehydrogenase I gene (IDH1) mutations occur in up to 80% of low-grade (WHO grade II) gliomas and about 5% of all glioblastomas (GBM) [1, 2]. IDH1 is also mutated in acute myeloid leukemia (AML) [3], cholangio-carcinomas, melanomas, chondrosarcomas, fibrosarcoma,

and other malignancies [4–6]. Despite being one of the few examples of a metabolic enzyme's mutation linked directly to cancer and its prevalence, the contribution of IDH1^{mut} enzyme activity to global tumor metabolism and its involvement in oncogenesis are not fully understood. The substitution of an arginine to a histidine (R132H) is the most common mutation (90%), and occurs in the active site of the enzyme leading to formation of 2-hydroxyglutarate (2HG) at the expense of α -ketoglutarate (α -KG) and NADPH [7–10]. 2HG has been previously reported to occur naturally [11, 12], although in lower

MLL2 conveys transcription-independent H3K4 trimethylation in oocytes

Courtney W. Hanna^{1,2}, Aaron Taudt^{3,4}, Jiahao Huang¹, Lenka Gahurova^{5,6}, Andrea Kranz⁷, Simon Andrews⁸, Wendy Dean¹, A. Francis Stewart^{7*}, Maria Colomé-Tatché^{3,4,9} and Gavin Kelsey^{1,2*}

Histone 3 K4 trimethylation (depositing H3K4me3 marks) is typically associated with active promoters yet paradoxically occurs at untranscribed domains. Research to delineate the mechanisms of targeting H3K4 methyltransferases is ongoing. The oocyte provides an attractive system to investigate these mechanisms, because extensive H3K4me3 acquisition occurs in nondividing cells. We developed low-input chromatin immunoprecipitation to interrogate H3K4me3, H3K27ac and H3K27me3 marks throughout oogenesis. In nongrowing oocytes, H3K4me3 was restricted to active promoters, but as oogenesis progressed, H3K4me3 accumulated in a transcription-independent manner and was targeted to intergenic regions, putative enhancers and silent H3K27me3-marked promoters. Ablation of the H3K4 methyltransferase gene *Mll2* resulted in loss of transcription-independent H3K4 trimethylation but had limited effects on transcription-coupled H3K4 trimethylation or gene expression. Deletion of *Dnmt3a* and *Dnmt3b* showed that DNA methylation protects regions from acquiring H3K4me3. Our findings reveal two independent mechanisms of targeting H3K4me3 to genomic elements, with MLL2 recruited to unmethylated CpG-rich regions independently of transcription.

INTRODUZIONE

Resting (non-growing) primordial follicles comprise the 'ovarian reserve', the size of which is a critical indicator of female fertility and the approximate determinant of reproductive lifespan¹. In women, the number of primordial

reproductive lifespan⁴. In women, the number of primordial follicles decreases from about 700,000 at the end of folliculogenesis² to about 1,000 when menopause ensues about age 51 (ref. 3). The initial pool of primordial follicles progressively decreases as follicles are recruited for ovulation¹. These processes are strictly regulated to prevent premature exhaustion of the primordial follicle reservoir (premature ovarian failure)⁴. Premature ovarian failure, defined by menopause before age 40, affects about 1% of women⁵.

How follicle recruitment is regulated is still largely unknown, but the forkhead transcription factor FOXO3 is strongly implicated. When *Foxo3* was ablated in mice, primordial follicles underwent massive and uncontrolled activation, leaving the ovary virtually empty and the females sterile by the age of 15 weeks⁶. This showed that *Foxo3* is required to maintain the follicle reserve pool. FOXO3 activity is regulated by phosphorylation: the unphosphorylated form is transcriptionally active in the nucleus; upon phosphorylation, the protein is exported to the cytoplasm, thereby losing transcriptional activity⁷. In the mouse ovary, cytoplasmic export of *Foxo3* in the oocytes coincides with the recruitment of follicles⁷.

Here, we test if this regulatory step is critical for follicle recruitment, that is, if FOXO3 function in the nucleus helps to maintain the follicle reserve pool. We generate a mouse model

MATERIALI E METODI

Mouse strains and husbandry. The transgene was generated by inserting a mutagenized human *FOXO3* sequence between a 6.3-kb mouse *Kit* promoter and a 0.6-kb 3'-flanking region from the human growth hormone (*GHI*) gene in a pUC18 vector (a generous gift of Dr J. A. Flaws). This construct was previously used to drive ovarian expression of a *Rcl2*

Microarray analysis. For each genotype, gonads from each of three pups were separately processed to provide replicates. Total RNA was extracted, amplified, purified (as above) and labelled for MouseWG-6 v2 Expression BeadChip arrays (Illumina). In order to test if the global transcriptional profile of *Foxo3* $-/-$ mice carrying the transgene had become similar to the normal profile compared with *Foxo3* $-/-$ mice without the transgene, we carried out unsupervised PCA on all 45 k probe levels normalized by Illumina proprietary software. In particular, we used the *svd* function in R to map the transgenic ovaries onto PCA space constructed based on the non-transgenic ovaries (Fig. 3b). This emphasized differences between *Foxo3* $-/-$ and *Foxo3* $+/-$ ovaries rather than between the presence or absence of the transgene. In order to test for an effect of the *FOXO3* transgene on ovarian maturation, we carried out PCA on our gonadal development data set and mapped a wide range of other gonadal samples that were published by others, as previously reported¹⁸. All these samples ($N=141$) were studied on the same Affymetrix platform. In order to map our current samples (which were done on a different platform, Illumina), we modified the procedure by adding a normalization step (centring to the median and reducing by the median absolute deviation from the median) and restricting the list of genes to the intersection between the 6 k probes that showed strongest differential expression in the Affymetrix samples and the top 5 k probes that showed strongest differential expression in the Illumina

Statistical analyses. For comparison of gonadotropin levels and follicle counts, statistical significance was calculated using the SAS program. Significance of cumulative number of progeny was calculated using a linear mixed-effect model (implemented in SAS). For gene expression using real-time PCR, statistical analysis was performed by the unpaired *t*-test (GraphPad).

Constitutively active Foxo3 in oocytes preserves ovarian reserve in mice, 2013, NATURE COMMUNICATIONS | 4:1843 | DOI: 10.1038/ncomms2861

RISULTATI

Expression of transgenic FOXO3. This FOXO3 transgene was placed under the control of a *Kit* promoter, assuring high expression in oocytes at the primordial and primary follicle stage¹⁰ (Fig. 1a). We verified the expression of the transgenic FOXO3 specifically by real-time PCR with construct-specific primers at birth (P0), 7 and 21 days (P7 and P21) (Fig. 1b). As follicle formation and maturation progressed, the level of FOXO3 decreased over time (Fig. 1b). However, *Foxo3* levels remained consistently higher in the transgenic ovaries when assayed with primers that detected both endogenous and transgene messenger RNA (Fig. 1c). The ratio of the expression of *Foxo3* in transgenic/wild-type ovaries remained constant at 1.44 ± 0.08 . Protein expression was also evaluated by western blot (Fig. 1d) at P7 and P21. Expression of FOXO3 was again confirmed with a stronger signal in the transgenic ovaries by band intensity analysis, thus consistent with RNA results (ratio of FOXO3 protein in transgenic/wild-type ovaries was 1.48 at P7 and 3.59 at P21).

Ovarian reserve retention is increased in FOXO3 mice. We next assessed the effects of the transgenic FOXO3 on follicle dynamics and ovarian aging. As menopause is preceded by a rise in follicle-stimulating hormone (FSH) and luteinizing hormone (LH)¹¹, we investigated whether follicle depletion occurred more

FOXO3 transgene preserves younger gene expression profiles.

To assess rate and extent of development in transgenic ovaries compared with wild-type, the expression of several oocyte and somatic genes involved in follicle maturation was evaluated. At P7, some follicles were already in the growing pool. Consistent with less follicle maturation in prepubertal transgenic mice (Fig. 3b), their ovaries showed significant downregulation of genes involved in follicle recruitment and/or growth, including *Gdf9*, *Bmp15*, *Amh*, *Cyp19a1* (aromatase) and *Kit-L*¹²⁻¹⁶ (Fig. 3c,d). By western blot analysis, the critical factors GDF9 and BMP15, expressed in

Discussione e Conclusioni

E' la sezione in cui gli autori interpretano i risultati ottenuti e ne analizzano il significato in relazione al problema di ricerca e alla letteratura esistente.

Deve contenere:

1. Interpretazione dei risultati: spiegazione del loro significato in termini scientifici e contestuali.
2. Confronto con studi precedenti: collegamenti o differenze rispetto ai risultati di altri lavori, evidenziando coerenze o discrepanze.
3. Implicazioni: implicazioni teoriche, pratiche o cliniche dei risultati.
4. Punti di forza e limiti: riflessione critica sulla metodologia e sui risultati, evidenziando eventuali limiti dello studio.
5. Prospettive future: indicazioni su ulteriori ricerche necessarie per approfondire il tema.

NOTA:

La discussione deve essere chiara, obiettiva e basata sui dati, evitando conclusioni speculative non supportate dai risultati.

ORIGINALITA'

RILEVANZA

More...

- Are methodology, Interpretation and statistics appropriate?
- Lack of key data (es. In vivo studies)
- Off/On target for the journal?
